We give conditions on a finitary endofunctor of a finitely accessible category to admit a final coalgebra. Our conditions always apply to the case of a finitary endofunctor of a locally finitely presentable (l.f.p.) category and they bring an explicit construction of the final coalgebra in this case. On the other hand, there are interesting examples of final coalgebras beyond the realm of l.f.p. categories to which our results apply. We rely on ideas developed by Tom Leinster for the study of self-similar objects in topology.

1. Introduction

Coalgebras for an endofunctor (of, say, the category of sets) are well-known to describe systems of formal recursive equations. Such a system of equations then specifies a potentially infinite “computation” and one is naturally interested in giving (uninterpreted) semantics to such a computation. In fact, such semantics can be given by means of a coalgebra again: this time by the final coalgebra for the given endofunctor.

Let us give a simple example of that.

Example 1.1. Suppose that we fix a set $A$ and we want to consider the set $A^\omega$ of infinite sequences of elements of $A$, called streams. Moreover, we want to define a function $\text{zip} : A^\omega \times A^\omega \to A^\omega$ that “zips up” two streams, i.e., the equality

$$\text{zip} \left( (a_0, a_1, a_2, \ldots), (b_0, b_1, b_2, \ldots) \right) = (a_0, b_0, a_1, b_1, a_2, b_2, \ldots)$$

holds.

One possible way of working with infinite expressions like streams is to introduce an additional approximation structure on the set of infinite expressions and to speak of an infinite expression as of a “limit” of its finite approximations, either in the sense of a complete partial order or of a complete metric space, see [ADJ] and [ARu], respectively. Such an approach may get rather technical and the additional approximation structure may seem rather arbitrary.

In fact, using the ideas of Calvin Elgot and his collaborators, see [E] and [EBT], combined with a coalgebraic approach to systems of recursive equations [R] and [AAMV], one may drop the additional structure altogether and define solutions by corecursion, i.e., by means of a final coalgebra.

Clearly, the above zipping function can be specified by a system of recursive equations

$$\text{zip}(a, b) = (\text{head}(a), \text{zip}(b, \text{tail}(a)))$$ (1.1)

one equation for each pair $a, b$ of streams, where we have used the functions $\text{head}(a_0, a_1, a_2, \ldots) = a_0$ and $\text{tail}(a_0, a_1, a_2, \ldots) = (a_1, a_2, \ldots)$.

In fact, the above system (1.1) of recursive equations can be encoded as a map

$$e : A^\omega \times A^\omega \to A \times A^\omega \times A^\omega, \quad (a, b) \mapsto (\text{head}(a), b, \text{tail}(a))$$ (1.2)

This means that we rewrote the system (1.1) as a coalgebra and we will show now that a final coalgebra gives its unique solution, namely the function $\text{zip}$. To this end, we define first an endofunctor $\Phi$ of the category of sets by the assignment

$$X \mapsto A \times X$$

A coalgebra for $\Phi$ (with an underlying set $X$) is then any mapping $e : X \to \Phi X$, i.e., a mapping of the form

$$e : X \to A \times X$$

Suppose that a final coalgebra

$$\tau : TA \to A \times TA$$

Date: 29 May 2009.

for \( \Phi \) exists. Its finality means that for any coalgebra \( c : Z \rightarrow A \times Z \) there exists a unique mapping \( c^\dagger : Z \rightarrow TA \) such that the square

\[
\begin{array}{ccc}
Z & \xrightarrow{c} & A \times Z \\
\downarrow & & \downarrow \\
TA & \xrightarrow{\tau} & A \times TA
\end{array}
\]  

(1.3)

commutes. Moreover, it is well-known that the mapping \( \tau \) must be a bijection due to finality. Luckily, in our case the final coalgebra is well-known to exist and has the following description: \( TA \) is the set of all streams \( A^\omega \) and the mapping \( \tau \) sends \( a \in A^\omega \) to the pair \((\text{head}(a), \text{tail}(a))\).

If we instantiate the coalgebra \( c \) from (1.2) in the above square and if we chase the elements of \( A^\omega \times A^\omega \) around it, we see that the uniquely determined function \( c^\dagger : A^\omega \times A^\omega \rightarrow A^\omega \) satisfies the recursive equation (1.1).

The reason for the existence of a final coalgebra for \( \Phi \) is that both the category of sets and the endofunctor \( \Phi \) are “good enough”: the category of sets is locally finitely presentable and the functor is finitary (we explain what that means in more detail below).

However, it is not the case that a final coalgebra exists for every “good enough” functor: for example the identity endofunctor of the category of sets and injections does not have a final coalgebra for cardinality reasons. Yet there are examples of interesting endofunctors of “less good” categories that still have a final coalgebra, see, e.g., Example 4.1 below.

The important thing, however, is that our uniform description of final coalgebras will be very reminiscent of streams: the coalgebra structure of a final coalgebra is always given by analogues of \( \text{head} \) and \( \text{tail} \) mappings from the previous example.

The goals and organization of the paper. In this paper we will focus on the existence of final coalgebras for the class of finitary endofunctors of finitely accessible categories. Moreover, we will give a concrete description of such coalgebras. From the above it is clear how final coalgebras capture solutions of recursive systems.

We will make advantage of the fact that finitary endofunctors of finitely accessible categories can be fully reconstructed from essentially small data. In fact, finitary endofunctors can be replaced by flat modules on the small categories of finitely presentable objects. Such pairs

\[
(\text{small category}, \text{flat module})
\]

will be called self-similarity systems and they fully encode the pattern of the recursive process in question.

We recall the concepts of finitary functors and finitely accessible categories and the process of passing from endofunctors to modules in Section 2.

In Section 3 we introduce the main tool of the paper — the category of complexes for a (flat) module. The category of complexes will then allow us to give a concrete description of final coalgebras.

In Section 4 we formulate a condition on the category of complexes that ensures that a final coalgebra for the module in question exists, see Theorem 4.12 below. As a byproduct we obtain, in Corollary 4.15, a new proof of the well-known fact that every finitary endofunctor of a locally finitely presentable category has a final coalgebra. Moreover, we prove that the elements of the final coalgebra are essentially the complexes.

Although the results of Section 4 give a concrete description of the final coalgebra, the condition we give in this section is rather strong. We devote Section 5 to a certain weakening of this condition. The weaker condition on the category of complexes of the module yields a final coalgebra as well but the module has to satisfy a certain side condition of finiteness flavour.

In some cases, one can prove that the conditions we give are necessary and sufficient for the existence of a final coalgebra. We devote Section 6 to finding conditions on the endofunctor that ensure the existence of such a characterization.

Related work. This work is very much influenced by the work of Tom Leinster, [Le1] and [Le2] on self-similarity in topology. In fact, Leinster works with categories that are “accessible” for the notion of componentwise filtered.

Other descriptions of final coalgebras follow from the analysis of the final coalgebra sequence, see [A1]. However, this technique differs from ours.

Acknowledgements. We are grateful to Tom Leinster and Jiří Adámek for their valuable comments on earlier drafts of this paper.
2. Preliminaries

In this preliminary section we introduce the notation and terminology that we will use in the rest of the paper. Most of it is fairly standard, we refer to books [AR] and [Bo] for the material concerning finitely accessible categories and finitary functors.

Coalgebras and final coalgebras. We give a precise definition of (final) coalgebras, see, e.g., [R] for motivation and examples of various coalgebras in the category of sets.

Definition 2.1. Suppose $\Phi : K \to K$ is any functor.

1. A coalgebra for $\Phi$ is a morphism $e : X \to \Phi(X)$.
2. A homomorphism of coalgebras from $e : X \to \Phi(X)$ to $e' : X' \to \Phi(X')$ is a morphism $h : X \to X'$ making the following square commutative.

\[
\begin{array}{ccc}
X & \xrightarrow{e} & \Phi(X) \\
\downarrow{h} & & \downarrow{\Phi(h)} \\
X' & \xrightarrow{e'} & \Phi(X')
\end{array}
\]

3. A coalgebra $\tau : T \to \Phi(T)$ is called final, if it is a terminal object of the category of coalgebras, i.e., if for every coalgebra $e : X \to \Phi(X)$ there is a unique morphism $e^\dagger : X \to T$ such that the square

\[
\begin{array}{ccc}
X & \xrightarrow{e} & \Phi(X) \\
\downarrow{e^\dagger} & & \downarrow{\Phi(e^\dagger)} \\
T & \xrightarrow{\tau} & \Phi(T)
\end{array}
\]

commutes.

Finitely accessible and locally finitely presentable categories. Finitely accessible and locally finitely presentable categories are those where every object can be reconstructed knowing its “finite parts”. This property has, for example, the category $\text{Set}$ of sets and mappings, where a set $P$ is recognized as finite exactly when its hom-functor $\text{Set}(P, -) : \text{Set} \to \text{Set}$ preserves colimits of a certain class — the so-called filtered colimits.

A colimit of a general diagram $D : \mathcal{D} \to \mathcal{K}$ is called filtered, provided that its scheme-category $\mathcal{D}$ is filtered. A category $\mathcal{D}$ is called filtered provided that every finite subcategory of $\mathcal{D}$ admits a cocone. In more elementary terms, filteredness of $\mathcal{D}$ can be expressed equivalently by the following three properties:

1. The category $\mathcal{D}$ is nonempty.
2. Each pair $d_1, d_2$ of objects of $\mathcal{D}$ has an “upper bound”, i.e., there exists a cocone

\[
\begin{array}{c}
d_1 \\
\downarrow{d} \\
d_2
\end{array}
\]

in $\mathcal{D}$.
3. Each parallel pair of morphisms in $\mathcal{D}$ can be “coequalized”, i.e., for each parallel pair

\[
\begin{array}{c}
d_1 \\
\overrightarrow{d} \\
d_2
\end{array}
\]

of morphisms in $\mathcal{D}$ there is a completion to a commutative diagram of the form

\[
\begin{array}{c}
d_1 \iff d_2 \to d
\end{array}
\]

in $\mathcal{D}$.

A category is $\mathcal{D}$ called cofiltered provided that the dual category $\mathcal{D}^{\text{op}}$ is filtered.

An object $P$ of a category $\mathcal{K}$ is called finitely presentable if the hom-functor $\mathcal{K}(P, -) : \mathcal{K} \to \text{Set}$ preserves filtered colimits.

Definition 2.2. A category $\mathcal{K}$ is called finitely accessible if it has filtered colimits and if it contains a small subcategory consisting of finitely presentable objects such that every object of $\mathcal{K}$ is a filtered colimit of these finitely presentable objects.

A cocomplete finitely accessible category is called locally finitely presentable.
Remark 2.3. Locally finitely presentable categories were introduced by Peter Gabriel and Friedrich Ulmer [GU], finitely accessible categories were introduced by Christian Lair [L] under the name sketchable categories. Tight connections of these concepts to (infinitary) logic can be found in the book [MPa], the book [AR] deals with the connection of these concepts to categories of structures.

Example 2.4.

1. The category Set of sets and mappings is locally finitely presentable. The finitely presentable objects are exactly the finite sets.
2. Every variety of finitary algebras is a locally finitely presentable category. The finitely presentable objects are exactly the algebras that are presented by finitely many generators and finitely many equations in the sense of universal algebra.
3. The category Inj having sets as objects and injective maps as morphisms is a finitely accessible category that is not locally finitely presentable. The finitely presentable objects are exactly the finite sets.
4. Denote by Field the category of fields and field homomorphisms. Then Field is a finitely accessible category that is not locally finitely presentable.
5. The category Lin of linear orders and monotone maps is finitely accessible but not locally finitely presentable. The finitely presentable objects are exactly the finite ordinals.
6. Let Pos_{0,1} denote the following category:
   (a) Objects are posets having distinct top and bottom elements.
   (b) Morphisms are monotone maps preserving top and bottom elements.
   Then Pos_{0,1} is a Scott complete category in the sense of Jiří Adámek [A2]: it is finitely accessible and every small diagram in Pos_{0,1} has a cocone, has a colimit.

Scott complete categories are therefore “not far away” from being cocomplete and thus locally finitely presentable. However, Pos_{0,1} is not locally finitely presentable since it lacks a terminal object. Finitely presentable objects in Pos_{0,1} are exactly the finite posets having distinct bottom and top elements.

7. The category of topological spaces and continuous maps is not finitely accessible. Although this category has filtered (in fact, all) colimits, the only finitely presentable objects are finite discrete topological spaces and these do not suffice for reconstruction of a general topological space.

Of course, more examples of “everyday-life” finitely accessible categories can be found in the literature, see, e.g., papers [D1] and [D2] by Yves Diers.

Every finitely accessible category $\mathbb{K}$ is equivalent to a category of the form 

$$\text{Flat}(\mathcal{A}, \text{Set})$$

(where $\mathcal{A}$ is a small category) that consists of all flat functors $X : \mathcal{A} \rightarrow \text{Set}$ and all natural transformations between them.

A functor $X : \mathcal{A} \rightarrow \text{Set}$ is called flat if its category of elements elts($X$) is cofiltered. The category elts($X$) has pairs $(x,a)$ with $x \in Xa$ as objects and as morphisms from $(x,a)$ to $(x',a')$ those morphisms $f : a \rightarrow a'$ in $\mathcal{A}$ with the property that $Xf(x) = x'$.

Flat functors $X$ can be characterized by any of the following equivalent conditions:

1. The functor $X : \mathcal{A} \rightarrow \text{Set}$ is a filtered colimit of representable functors.
2. The left Kan extension $\text{Lan}_X : [\mathcal{A}^{\text{op}}, \text{Set}] \rightarrow \text{Set}$ of $X : \mathcal{A} \rightarrow \text{Set}$ along the Yoneda embedding $Y : \mathcal{A} \rightarrow [\mathcal{A}^{\text{op}}, \text{Set}]$ preserves finite limits.

In case when $\mathbb{K}$ is locally finitely presentable one can prove that $\mathbb{K}$ is equivalent to the category

$$\text{Lex}(\mathcal{A}, \text{Set})$$

of all finite-limits-preserving functors on a small finitely complete category $\mathcal{A}$. In fact, the flat functors are exactly the finite-limits-preserving ones in this case.

Example 2.5. In this example we show how to express Set as a category of flat functors. Denote by $E : \text{Set}_{fp} \rightarrow \text{Set}$ the full dense inclusion of an essentially small category of finite sets. In fact, in this example, we choose as a representative set of finitely presentable objects the set of finite ordinals.

The correspondence

$$X \mapsto \text{Set}(E-, X)$$

then provides us with an equivalence

$$\text{Set} \simeq \text{Flat}(\text{Set}_{fp}^{\text{op}}, \text{Set}) = \text{Lex}(\text{Set}_{fp}^{\text{op}}, \text{Set})$$
of categories. The slogan behind this correspondence is the following one:

Instead of describing a set $X$ by means of its elements $x \in X$ (as we do in $\text{Set}$), we describe a set by “generalized elements” of the form $n \rightarrow X$, where $n$ is a finite ordinal.

Thus, a set $X$ now “varies in time”: the hom-set $\text{Set}(n, X)$ is the “value” of $X$ at “time” $n$.

**Remark 2.6.** The above example is an instance of a general fact: every finitely accessible category $\mathcal{K}$ is equivalent to $\text{Flat}(\mathcal{K}_{fp}^{op}, \text{Set})$, where $E : \mathcal{K}_{fp} \rightarrow \mathcal{K}$ denotes the full inclusion of the essentially small subcategory consisting of finitely presentable objects.

The equivalence works as follows: the flat functor $X : \mathcal{K}_{fp}^{op} \rightarrow \text{Set}$ is sent to the object

$$X \star E$$

which is a colimit of $E$ weighted by $X$. Such a colimit is defined as an object $X \star E$ together with an isomorphism

$$\mathcal{K}(X \star E, Z) \cong [\mathcal{K}_{fp}^{op}, \text{Set}](X, \mathcal{K}(E-, Z))$$

natural in $Z$. The above colimit can be considered to be an “ordinary” colimit of the diagram of elements of $X$:

$$x \in Xa \mapsto Ea$$

This explains the weight terminology: every $Ea$ is going to be counted “$Xa$-many times” in the colimit $X \star E$. See [Bo] for more details.

**Flat modules.** On finitely accessible categories there is class of functors that can be fully reconstructed by knowing their values on “finite parts”. An example is the finite-powerset endofunctor $P_{\text{fin}} : X \mapsto \{S \mid S \subseteq X, S \text{ is finite }\}$ of the category of sets. Such endofunctors can be characterized as exactly those preserving filtered colimits.

**Definition 2.7.** A functor $\Phi : \mathcal{K} \rightarrow \mathcal{L}$ between finitely accessible categories is called *finitary* if it preserves filtered colimits.

By the above considerations, every finitary endofunctor $\Phi : \mathcal{K} \rightarrow \mathcal{K}$ of a finitely accessible category $\mathcal{K}$ can be considered, to within equivalence, as a finitary endofunctor

$$\Phi : \text{Flat}(\mathcal{A}, \text{Set}) \rightarrow \text{Flat}(\mathcal{A}, \text{Set})$$

Since the full embedding $\mathcal{A}^{op} \rightarrow \text{Flat}(\mathcal{A}, \text{Set})$ exhibits $\text{Flat}(\mathcal{A}, \text{Set})$ as a free cocompletion of $\mathcal{A}^{op}$ w.r.t. filtered colimits, we can then reconstruct $\Phi$ from a mere functor

$$M_{\Phi} : \mathcal{A}^{op} \rightarrow \text{Flat}(\mathcal{A}, \text{Set})$$

(no preservation properties) by means of filtered colimits.

The latter functor can be identified with a functor of the form $M_{\Phi} : \mathcal{A}^{op} \times \mathcal{A} \rightarrow \text{Set}$ with the property that every $M_{\Phi}(a, -) : \mathcal{A} \rightarrow \text{Set}$ is flat. Such functors of two variables (without the extra flatness property) are commonly called modules. We will give the extra property a name.

**Definition 2.8.** A module $M : \mathcal{A} \rightarrow \mathcal{B}$ from a small category $\mathcal{A}$ to a small category $\mathcal{B}$ is a functor $M : \mathcal{A}^{op} \times \mathcal{A} \rightarrow \text{Set}$. Given two such modules, $M$ and $N$, a module morphism $M \rightarrow N$ is a natural transformation between the respective functors.

A module $M$ as above is called *flat* if every partial functor $M(a, -) : \mathcal{B} \rightarrow \text{Set}$ is a flat functor in the usual sense.

**Remark 2.9.** The above module terminology makes perfect sense if we denote an element $m \in M(a, b)$ by an arrow

$$a \xrightarrow{m} b$$

and think of it as of a “vector” on which the categories $\mathcal{A}$ and $\mathcal{B}$ can act by means of their morphisms (“scalars”):

1. Given $f : a' \rightarrow a$ in $\mathcal{A}$, then

$$a' \xrightarrow{f} a \xrightarrow{m} b$$

 denotes the element $M(f, b)(m) \in M(a', b)$.

Had we denoted such an action by $m \circ f$, then it is obvious that equations $m \circ (f \cdot f') = (m \circ f) \circ f'$ and $m \circ 1_a = m$ hold — something that we know from classical module theory.
(2) Given \( g : b \rightarrow b' \) in \( \mathcal{B} \), then
\[
\begin{array}{c}
a \xrightarrow{m} b \xrightarrow{g} b'
\end{array}
\]
denotes the element \( M(a, g)(m) \in M(a, b') \).

(3) Functoriality of \( M \) gives an unambiguous meaning to diagrams of the form
\[
\begin{array}{c}
a' \xrightarrow{f} a \xrightarrow{m} b \xrightarrow{g} b'
\end{array}
\]
(4) We also extend the notion of commutative diagrams. For example, by saying that the following square
\[
\begin{array}{c}
a \xrightarrow{m} b \\
\downarrow{f} \\
a' \xrightarrow{m'} b'
\end{array}
\]
commutes we mean that the equality \( m'@f = g@m \) holds.

Remark 2.10. The broken arrow notation also allows us to formulate flatness of a module \( M : \mathcal{A} \rightarrow \mathcal{B} \) in elementary terms. Namely, for every \( a \) in \( \mathcal{A} \) the following three conditions must be satisfied:

1. There is a broken arrow
\[
\begin{array}{c}
a \xrightarrow{\eta} b
\end{array}
\]
for some \( b \) in \( \mathcal{B} \).
2. For any two broken arrows
\[
\begin{array}{c}
a \xrightarrow{m_1} b_1 \\
\downarrow{m_2} \\
a \xrightarrow{m_2} b_2
\end{array}
\]
there is a commutative diagram
\[
\begin{array}{c}
a \xrightarrow{m_1} b_1 \\
\downarrow{f_1} \\
a \xrightarrow{m_2} b_2 \\
\downarrow{f_2}
\end{array}
\]
3. For every commutative diagram
\[
\begin{array}{c}
a \xrightarrow{m_1} b_1 \\
\downarrow{s} \\
a \xrightarrow{m_2} b_2
\end{array}
\]
there is a commutative diagram
\[
\begin{array}{c}
a \xrightarrow{m_1} b_1 \\
\downarrow{f} \\
a \xrightarrow{m_2} b_2 \\
\downarrow{s}
\end{array}
\]

Example 2.11. In this example we show how the finitary endofunctor
\[
X \mapsto X \times X + A
\]
of the locally finitely presentable category \( \text{Set} \) can be viewed as a flat module.

In this sense, we identify the endofunctor \( X \mapsto X \times X + A \) of \( \text{Set} \) with the endofunctor
\[
\Phi : \text{Set}(E -, X) \mapsto \text{Set}(E -, X \times X) + \text{Set}(E -, A)
\]
of \( \text{Flat}(\text{Set}_{fp}^{op}, \text{Set}) \). The corresponding flat module
\[
M : \text{Set}_{fp}^{op} \longrightarrow \text{Set}_{fp}^{op}
\]
then has values

\[ M(a, b) = \text{Set}_{fp}(b, a \times a) + \text{Set}(b, A) \]

at finite ordinals \(a, b\).

The above resemblance to classical module theory\(^1\) can be pushed further: modules can composed by “tensoring” them.

**Definition 2.12.** Suppose \( M : \mathcal{A} \to \mathcal{B} \) and \( N : \mathcal{B} \to \mathcal{C} \) are modules. By

\[ N \otimes M : \mathcal{A} \to \mathcal{C} \]

we denote their composition which is defined objectwise by means of a coend

\[ (N \otimes M)(a, c) = \int^b N(b, c) \times M(a, b) \]

**Remark 2.13.** A coend is a special kind of colimit. The elements of \( (N \otimes M)(a, c) \) are equivalence classes. A typical element of \( (N \otimes M)(a, c) \) is an equivalence class \([ (n, m) ]\) represented by a pair \((n, m) \in N(b, c) \times M(a, b)\) where the equivalence is generated by requiring the pairs

\[ (n, f \circ m) \quad \text{and} \quad (n \circ f, m) \]

to be equivalent, where \(n, f\) and \(m\) are as follows:

\[ a \overset{m}{\to} b \overset{f}{\to} b' \overset{\eta}{\to} c \]

Above, we denoted the actions of \(M\) and \(N\) by the same symbols, not to make the notation heavy.

It is well-known (see [Bo]) that the above composition organizes modules into a bicategory: the composition is associative only up to a coherent isomorphism and the identity module \( \mathcal{A} : \mathcal{A} \to \mathcal{A} \), sending \((a', a)\) to the hom-set \( \mathcal{A}(a', a) \), serves as a unit only up to a coherent isomorphism. The following result is then easy to prove.

**Lemma 2.14.** Every identity module is flat and composition of flat modules is a flat module.

**Remark 2.15.** The above composition of modules makes one to attempt to draw diagrams such as

\[ a_2 \overset{m_2}{\to} a_1 \overset{m_1}{\to} a_0 \]

for elements \(m_1 \in M(a_1, a_0), m_2 \in M(a_2, a_1)\) of a module \(M : \mathcal{A} \to \mathcal{A}\). Such diagrams are, however, to be considered only formally — we never compose two “broken” arrows.

The tensor notation from the above paragraphs allows us to pass from endofunctors to modules completely.

Observe that any flat functor \(X : \mathcal{A} \to \text{Set}\) can be considered as a flat module \(X : 1 \to \mathcal{A}\) where \(1\) denotes the one-morphism category.

Then, given a flat module \(M : \mathcal{A} \to \mathcal{A}\), the assignment \(X \mapsto M \otimes X\) defines a finitary endofunctor of \(\text{Flat}(\mathcal{A}, \text{Set})\).

In fact, every finitary endofunctor \(\Phi\) of \(\text{Flat}(\mathcal{A}, \text{Set})\) arises in the above way: construct the flat module \(M_\Phi\) as above, then there is an isomorphism

\[ \Phi \cong M_\Phi \otimes - \]

of functors.

### 3. The category of complexes and self-similarity systems

Formal chains of “broken arrows” will be the main tool of the rest of the paper. We define a category of such chains (this definition comes from the paper [Le1] of Tom Leinster).

**Assumption 3.1.** In the rest of the paper,

\[ M : \mathcal{A} \to \mathcal{A} \]

denotes a flat module on a small category \(\mathcal{A}\). The pair \((\mathcal{A}, M)\) is called a self-similarity system.

**Remark 3.2.** The terminology self-similarity system is due to Tom Leinster [Le1] and has its origin in the intention to study (topological) spaces that are self-similar. Since we refer to [Le1] below, we keep the terminology, although our motivation is different.

\(^1\)The resemblance can be made precise by passing to enriched category theory, see [Bo].
**Definition 3.3.** Given a (flat) module $M$, the category $\text{Complex}(M)$ of $M$-complexes and their morphisms is defined as follows:

1. Objects, called $M$-complexes, are countable chains of the form
   $$\ldots \xrightarrow{m_3} a_2 \xrightarrow{m_2} a_1 \xrightarrow{m_1} a_0$$
   A single complex as above will be denoted by $(a_\bullet, m_\bullet)$ for short.

2. Morphisms from $(a_\bullet, m_\bullet)$ to $(a'_\bullet, m'_\bullet)$ are sequences $f_n : a_n \rightarrow a'_n$, denoted by $(f_\bullet)$, such that all squares in the following diagram
   $$\begin{array}{ccc}
   \ldots & a_2 & a_1 & a_0 \\
   & \downarrow{f_2} & \downarrow{f_1} & \downarrow{f_0} \\
   \ldots & a'_2 & a'_1 & a'_0
   \end{array}$$
   commute.

For $n \geq 0$, we denote by $\text{Complex}_n(M)$ the category of $n$-truncated $M$-complexes. Its objects are finite chains
$$a_n \xrightarrow{m_n} a_{n-1} \xrightarrow{\ldots} a_2 \xrightarrow{m_2} a_1 \xrightarrow{m_1} a_0$$
and the morphisms of $\text{Complex}_n(M)$ are defined in the obvious way.

The obvious truncation functors are denoted by $\text{pr}_n : \text{Complex}(M) \rightarrow \text{Complex}_n(M), \ n \geq 0$

Observe that $\text{Complex}_0(M) = \mathcal{A}$.

**Example 3.4.** Recall the flat module $M$ of Example 2.11 that corresponds to the finitary endofunctor $X \mapsto X \times X + A$ of sets.

An $M$-complex
$$\ldots \xrightarrow{m_3} a_2 \xrightarrow{m_2} a_1 \xrightarrow{m_1} a_0$$

can be identified with a “binary tree” of maps of the form

where each path is either infinite or it ends with a generalized element of $A$.

**Remark 3.5.** The description of complexes is particularly simple if one starts with a finitely accessible category $\mathcal{K}$ and a finitary endofunctor $\Phi : \mathcal{K} \rightarrow \mathcal{K}$. Then a complex (for the module corresponding to $\Phi$) is just a sequence
$$a_0 \xrightarrow{m_1} \Phi(a_1), \ a_1 \xrightarrow{m_2} \Phi(a_2), \ a_2 \xrightarrow{m_3} \Phi(a_3), \ \ldots$$

of morphisms in $\mathcal{K}$, where all the objects $a_0, a_1, a_2, \ldots$ are finitely presentable.
And morphisms of complexes are just sequences of morphisms in $\mathcal{K}$ making the obvious squares commutative:

\[
\begin{array}{cccc}
a_0 & \xrightarrow{m_1} & \Phi(a_1) \\
f_0 & \downarrow & \Phi(f_1) \\
a_0' & \xrightarrow{m_1'} & \Phi(a_1')
\end{array}
\quad
\begin{array}{cccc}
a_1 & \xrightarrow{m_2} & \Phi(a_2) \\
f_1 & \downarrow & \Phi(f_2) \\
a_1' & \xrightarrow{m_2'} & \Phi(a_1')
\end{array}
\quad
\begin{array}{cccc}
a_2 & \xrightarrow{m_3} & \Phi(a_3) \\
f_2 & \downarrow & \Phi(f_3) \\
a_2' & \xrightarrow{m_3'} & \Phi(a_2')
\end{array}
\ldots
\]

In fact, a complex seen in this way is a “finitary bit” of a general coalgebra in the following sense: start with a coalgebra $c : X \rightarrow \Phi(X)$ and a morphism $f_0 : a_0 \rightarrow X$, where $a_0$ is finitely presentable. Due to finitary of $\Phi$, the composite $c \cdot f_0 : a_0 \rightarrow \Phi(X)$ factors through $\Phi(f_1) : \Phi(a_1) \rightarrow \Phi(X)$ where $a_1$ is finitely presentable. The factorizing map $m_1 : a_0 \rightarrow \Phi(a_1)$ is then the germ of a complex: proceed with $f_1 : a_1 \rightarrow X$ to obtain $m_2 : a_1 \rightarrow \Phi(a_2)$, etc.

## 4. The Strong Solvability Condition

The Strong Solvability Condition on a self-similarity system $(\mathcal{A}, M)$ will give us a final coalgebra for the finitary functor

$$M \otimes - : \text{Flat}(\mathcal{A}, \text{Set}) \rightarrow \text{Flat}(\mathcal{A}, \text{Set})$$

almost “for free”. The condition asserts that there is a certain filtered diagram of representables in $\text{Flat}(\mathcal{A}, \text{Set})$. The carrier of the final coalgebra is simply its colimit, see Theorem 4.12 below.

Although the condition is rather strong and hard to verify in practice (and we will seek a weaker one in next section), it is trivially satisfied in the realm of locally finitely presentable categories. Hence the technique of the current section enables us to give a uniform description of final coalgebras for finitary endofunctors of locally finitely presentable categories, see Corollary 4.15.

Most of the results of this section are reformulations of things proved in [Le1] by Tom Leinster into our setting.

We give first an example of a finitely accessible category $\mathcal{K}$ that is not locally finitely presentable and a finitary endofunctor $\Phi : \mathcal{K} \rightarrow \mathcal{K}$ that admits a final coalgebra.

**Example 4.1.** Recall the category $\text{Pos}_{0,1}$ of all posets having distinct top and bottom and all monotone maps preserving top and bottom of Example 2.4(6). Recall that $\text{Pos}_{0,1}$ is finitely accessible but not locally finitely presentable.

It has been shown by Peter Freyd [F] that there is a finitary endofunctor $\Phi$ of $\text{Pos}_{0,1}$ whose final coalgebra gives the unit interval $[0, 1]$.

The functor $\Phi : \text{Pos}_{0,1} \rightarrow \text{Pos}_{0,1}$ sends $X$ to the smash coproduct

$$X \vee X$$

of $X$ with itself that is defined as follows: put one copy of $X$ on top of the other one and glue the copies together by identifying top and bottom. More formally, $X \vee X$ is the subposet of $X \times X$ consisting of pairs $(x, 0)$ or $(1, y)$. The pairs $(x, 0)$ are going to be called living in the left-hand copy of $X$ and the pairs of the form $(1, y)$ as living in the right-hand copy.

Clearly, given a coalgebra $c : X \rightarrow X \vee X$ and $x \in X$, one can produce at least one infinite sequence

$$x_1 x_2 x_3 \ldots$$

of 0’s and 1’s as follows: look at $c(x)$ and put $x_1 = 0$ if it is in the left-hand copy of $X$, put $x_1 = 1$ otherwise. Then regard $c(x)$ as an element of $X$ again, apply $c$ to it to produce $x_2$, etc.

One needs to show that the binary expansion $c^1(x) = x_0 x_1 x_2 x_3 \ldots$ so obtained can be used to define a map $c^1 : X \rightarrow [0, 1]$ in a clash-free way (i.e., regardless of the fact that sometimes we may have a choice in defining $x_k = 0$ or $x_k = 1$). Moreover, the above map $c^1$ is then a witness that the coalgebra

$$t : [0, 1] \rightarrow [0, 1] \vee [0, 1]$$

where $[0, 1]$ denotes the closed unit interval with the usual order and $t$ given by putting $t(x) = (2x, 0)$ for $0 \leq x \leq 1/2$ and $t(x) = (1, 2x - 1)$ otherwise, is a final coalgebra for $\Phi$.

See [F] for more details on finality of $[0, 1]$ and see Example 4.14 below that the description of a final coalgebra for $\Phi$ given by our theory will provide us with the unit interval canonically.

We introduce now a condition on a self-similarity system $(\mathcal{A}, M)$ that will ensure the existence of a final coalgebra.
Remark 4.4. In elementary terms, the Strong Solvability Condition says that the following three conditions of representables is filtered. Its colimit (a flat functor!) is going to be the carrier of the final coalgebra for $\mathcal{M} \otimes -$ , see Theorem 4.12 below.

Remark 4.3. The Strong Solvability Condition implies that the diagram

$$\left( \text{Complex}(\mathcal{M}) \right)^{op} \xrightarrow{\mathcal{M}^{op}} \mathcal{M}^{op} \xrightarrow{Y} [\mathcal{M}, \text{Set}]$$

of representables is filtered. Its colimit (a flat functor!) is going to be the carrier of the final coalgebra for $\mathcal{M} \otimes -$ , see Theorem 4.12 below.

Definition 4.2. We say that $(\mathcal{A}, M)$ satisfies the Strong Solvability Condition if the category $\text{Complex}(M)$ is cofiltered.

Remark 4.4. In elementary terms, the Strong Solvability Condition says that the following three conditions hold:

1. The category $\text{Complex}(M)$ is nonempty.
2. For every pair $(a_\bullet, m_\bullet), (a'_\bullet, m'_\bullet)$ in $\text{Complex}(M)$ there is a span

$$\begin{array}{ccc}
(a_\bullet, m_\bullet) & \xrightarrow{(f_\bullet)} & (a'_\bullet, m'_\bullet) \\
(b_\bullet, n_\bullet) & \xrightarrow{(f'_\bullet)} & (a'_\bullet, m'_\bullet)
\end{array}$$

in $\text{Complex}(M)$.
3. For every parallel pair of the form

$$\begin{array}{ccc}
(a_\bullet, m_\bullet) & \xrightarrow{(u_\bullet)} & (a'_\bullet, m'_\bullet) \\
(b_\bullet, n_\bullet) & \xrightarrow{(u'_\bullet)} & (a'_\bullet, m'_\bullet)
\end{array}$$

in $\text{Complex}(M)$ there is a fork

$$\begin{array}{ccc}
(b_\bullet, n_\bullet) & \xrightarrow{(f_\bullet)} & (a_\bullet, m_\bullet) & \xrightarrow{(u_\bullet)} & (a'_\bullet, m'_\bullet)
\end{array}$$

in $\text{Complex}(M)$.

Example 4.5. (Continuation of Example 4.1.)

We show that the self-similarity system $(\mathcal{A}, M)$ corresponding to the functor $\Phi : \text{Pos}_{0,1} \rightarrow \text{Pos}_{0,1}$ of Example 4.1 satisfies the Strong Solvability Condition.

Recall that $M$ is defined as

$$M(a,b) = \text{Pos}_{0,1}(b, a \lor a)$$

where the posets $a$, $b$ are finite (having distinct bottom and top).

A complex $(a_\bullet, m_\bullet)$ is therefore a chain

$$m_1 : a_0 \rightarrow a_1 \lor a_1, \quad m_2 : a_1 \rightarrow a_2 \lor a_2, \quad \ldots, \quad m_i : a_i \rightarrow a_{i+1} \lor a_{i+1}, \quad \ldots$$

of morphisms in $\text{Pos}_{0,1}$.

We have to show that $\text{Complex}(M)$ is cofiltered and we will use the elementary description of complexes of Remark 3.5 and the elementary description of cofilteredness of Remark 4.4:

1. $\text{Complex}(M)$ is nonempty.
   Let $a_1 = 2$, the two-element chain, for every $i \geq 0$ and, for all $i \geq 0$, let $m_1 : a_i \rightarrow a_{i+1} \lor a_{i+1}$ be the unique morphism in $\text{Pos}_{0,1}$. This defines a complex.

2. $\text{Complex}(M)$ has cones for two-element discrete diagrams.
   Suppose $(a_\bullet, m_\bullet)$ and $(a'_\bullet, m'_\bullet)$ are given. Hence we have chains

$$m_1 : a_0 \rightarrow a_1 \lor a_1, \quad m_2 : a_1 \rightarrow a_2 \lor a_2, \quad \ldots, \quad m_i : a_i \rightarrow a_{i+1} \lor a_{i+1}, \quad \ldots$$

and

$$m'_1 : a'_0 \rightarrow a'_1 \lor a'_1, \quad m'_2 : a'_1 \rightarrow a'_2 \lor a'_2, \quad \ldots, \quad m'_i : a'_i \rightarrow a'_{i+1} \lor a'_{i+1}, \quad \ldots$$

Since every pair $a_i, a'_i$ has a cocone in $(\text{Pos}_{0,1})_{fp}$, every pair $a_i, a'_i$ has a coproduct $a_i + a'_i$ in $(\text{Pos}_{0,1})_{fp}$ due to Scott-completeness of $\text{Pos}_{0,1}$, see Example2.4(6).

One then uses flatness of $M$ to obtain the desired vertex $(b_\bullet, n_\bullet)$ of a cone as follows: put $b_i = a_i + a'_i$ for all $i \geq 0$ and define $n_i : b_i \rightarrow b_{i+1} \lor b_{i+1}$ to be the one given by the bijection

$$\text{Pos}_{0,1}(b_i, b_{i+1} \lor b_{i+1}) = \text{Pos}_{0,1}(a_i + a'_i, b_{i+1} \lor b_{i+1}) \cong \text{Pos}_{0,1}(a_i, b_{i+1}) \times \text{Pos}_{0,1}(a'_i, b_{i+1})$$
applied to the obvious pair of morphisms $a_i \to b_i+1, a_i' \to b_i+1$.

(3) $\text{Complex}(M)$ has cones for parallel pairs.

This follows immediately from the following claim:

There are no serially commutative squares

$$
\begin{array}{ccc}
X & \xrightarrow{u} & Y \\
\downarrow{s} & & \downarrow{r} \\
Z \lor Z & \xrightarrow{h \lor l} & W \lor W
\end{array}
$$

whenever the maps $u, d$ cannot be coequalized.

Notice first that both $h \lor h$ and $l \lor l$ map the “middle element” $(1, 0)$ of $Z \lor Z$ to the respective “middle element” in $W \lor W$.

Next notice that the only reason for which $u$ and $d$ cannot be coequalized is that some $x \in X$ is sent to 0 by $d$ and to 1 by $u$. Fix this $x$, and notice that equations $ru(x) = 1$ and $rd(x) = 0$ hold.

Notice also that

$$H_h = \{z \in Z \lor Z \mid (h \lor h)(z) = 1\}$$

is a proper subset of $\{z \in Z \lor Z \mid z \geq m\}$ where $m$ denotes the “middle element” of $Z \lor Z$.

Similarly,

$$H_l = \{z \in Z \lor Z \mid (l \lor l)(z) = 0\}$$

is a proper subset of $\{z \in Z \lor Z \mid z \leq m\}$.

Especially, $H_h \cap H_l = \emptyset$.

Suppose that the diagram (4.1) serially commutes. Then $s(x) \in H_h \cap H_l$, a contradiction.

In the above example we exploited the existence of binary products in $\mathcal{A} = (\text{Pos}_{0,1})^{op}$ to observe that one can construct cones for two-element diagrams in $\text{Complex}(M)$. This is a general fact as the next result shows.

**Proposition 4.6.** Suppose $\mathcal{A}$ has nonempty finite limits. Then the category $\text{Complex}(M)$ is cofiltered.

**Proof.** Due to Assumption 4.10, the empty diagram in $\text{Complex}(M)$ has a cone.

Suppose that

$$D : \mathcal{D} \to \text{Complex}(M)$$

with $\mathcal{D}$ finite and nonempty, is given. Let us put

$$Dd = \begin{array}{cccccc}
\cdots & m_3^d & a_3^d & m_2^d & a_2^d & m_1^d & a_1^d & \cdots \\
\downarrow{\delta_2} & \downarrow{\delta_1} & \downarrow{\delta_0} & & & & \\
\cdots & m_3^d & a_3^d & m_2^d & a_2^d & m_1^d & a_1^d & \cdots
\end{array}$$

and observe that, for each $n \geq 0$, its $n$-th coordinate provides us with a diagram of shape $\mathcal{D}$ in $\mathcal{A}$. Since $\mathcal{A}$ has finite nonempty limits, we can denote, for each $n \geq 0$, by

$$c_n^d : a_n \to a_n^d$$

the limit of the $n$-th coordinate.

For each $n \geq 0$, we define $m_{n+1} \in M(a_{n+1}, a_n)$ as follows: since

$$M(a_{n+1}, a_n) \cong \lim_d M(a_{n+1}, a_n^d)$$

holds by flatness of $M$, there is a unique $m_{n+1}$ such that the square

$$\begin{array}{ccc}
a_{n+1} & \xrightarrow{m_{n+1}} & a_n \\
\downarrow{c_n^d} & & \downarrow{c_n^d} \\
a_{n+1}^d & \xrightarrow{m_{n+1}^d} & a_n^d
\end{array}$$

commutes.
The complex \((a_\bullet, m_\bullet)\) defined in the above manner is easily seen to be a limit of \(D : \mathcal{A} \to \text{Complex}(M)\). This finishes the proof that \(\text{Complex}(M)\) is cofiltered, hence \((\mathcal{A}, M)\) satisfies the Strong Solvability Condition. 

The Strong Solvability Condition requires, by Remark 4.4, the category \(\text{Complex}(M)\) to be nonempty. This is no restriction as the following lemma shows.

**Lemma 4.7.** Either there exists no coalgebra for \(M \otimes -\) or the category \(\text{Complex}(M)\) is nonempty.

**Proof.** Suppose that \(e : X \to M \otimes X\) is some coalgebra. The functor \(X\) must be flat, hence there exists an element \(x_0 \in Xa_0\). Consider the element \(e_{a_0}(x_0) \in (M \otimes X)(a_0)\). Since

\[
(M \otimes X)(a_0) = \int^a M(a, a_0) \times Xa
\]

there exist \(a_1, m_1 \in M(a_1, a_0)\) and \(x_1 \in Xa_1\) such that the pair \((m_1, x_2)\) represents \(e_{a_0}(x_0)\). It is clear that in this way we can construct a complex, a contradiction. 

**Definition 4.8.** The complex \((a_\bullet, m_\bullet)\) together with the sequence \((x_a)\) constructed in the above proof is called an \(e\)-resolution of \(x_0 \in Xa_0\).

**Remark 4.9.** The above construction of an \(e\)-resolution indicates that a coalgebra \(e : X \to M \otimes X\) is a system of recursive equations that “varies in time”. For at “time” \(a_0\) we can write the system of formal recursive equations

\[
x_0 \equiv m_1 \otimes x_1 \\
x_1 \equiv m_2 \otimes x_2 \\
\vdots
\]

where \((x_a)\) and \((a_\bullet, m_\bullet)\) form the \(e\)-resolution of \(x_0 \in Xa_0\). Above, we use the tensor notation to denote, e.g., by \(m_1 \otimes x_1\) the element of \(\int^a M(a, a_0) \times Xa\) represented by the pair \((m_1, x_1)\).

Of course, any “evolution of time” \(f : a_0 \to a_0'\) provides us with a compatible corresponding recursive system starting at \(x'_0 = Xf(x_0) \in Xa_0'\).

**Assumption 4.10.** We assume further on that \(\text{Complex}(M)\) is a nonempty category.

**Remark 4.11.** The proof of the following theorem is a straightforward modification of the proof of Theorem 5.11 of [Le0]. The reason is that our definition of the carrier of the final coalgebra (as a certain colimit) coincides with the definition of Tom Leinster’s (as being pointwise a set of connected components of a certain diagram, see Theorem 2.1 of [Pa]). Observing this, the reasoning of the proof goes exactly as in [Le0].

**Theorem 4.12.** Any \((\mathcal{A}, M)\) satisfying the Strong Solvability Condition admits a final coalgebra for \(M \otimes -\).

**Proof.** Define \(I : \mathcal{A} \to \text{Set}\) to be the colimit of the diagram

\[
\left(\text{Complex}(M)\right)^{op} \xrightarrow{m_{a_0}^\circ} \mathcal{A}^{op} \xrightarrow{Y} [\mathcal{A}, \text{Set}]
\]

By the Strong Solvability Condition, \(I\) is a flat functor, being a filtered colimit of representables. Observe that \(x \in Ia\) is an equivalence class of complexes of the form

\[
\cdots \xrightarrow{m_3} a_2 \xrightarrow{m_2} a_1 \xrightarrow{m_1} a_0 = a
\]

where two such complexes are equivalent if and only if there is a zig-zag of complex morphisms having identity on \(a\) as the 0-th component. Thus it is exactly the description of elements of a final coalgebra that Tom Leinster has for his setting in [Le0], page 25. We denote equivalence classes by square brackets.

We define the coalgebra structure \(\iota : I \to M \otimes I\) objectwise. For each \(a \in \mathcal{A}\)

\[
\iota_a : Ia \to (M \otimes I)(a) = \int^a M(a', a) \times Ia'
\]

is a map sending the equivalence class

\[
[\cdots \xrightarrow{m_3} a_2 \xrightarrow{m_2} a_1 \xrightarrow{m_1} a_0 = a]
\]

to the element

\[
a_1 \xrightarrow{m_1} a_0 \otimes [\cdots \xrightarrow{m_3} a_2 \xrightarrow{m_2} a_1]
\]

of \((M \otimes I)(a)\) (recall the tensor notation of Remark 4.9).
By Proposition 5.8 of [Le1] such $\iota$ is a natural isomorphism. That $\iota : I \to M \otimes I$ is a final coalgebra follows from Theorem 5.11 of [Le1], once we have verified that $I$ is flat. Tom Leinster proves finality with respect to componentwise flat functors so, a fortiori, the coalgebra $\iota$ is final with respect to coalgebras whose carriers are flat functors. 

**Remark 4.13.** Observe that (the $a$-th component of) the mapping $\epsilon_a : Ia \to (M \otimes I)(a)$ is indeed very similar to the coaugural structure $\tau = (\text{head}, \text{tail})$ of the final coalgebra of streams of Example 1.1.

**Example 4.14.** (Continuation of Examples 4.1 and 4.5.)

We indicate how the description of the final coalgebra for the squaring functor on the category $\text{Pos}_{0,1}$ that we gave in Example 4.1 corresponds to the description given by the proof of Theorem 4.12.

We denote the module, corresponding to the squaring functor $X \mapsto X \vee X$, by $M$. Observe that

$$M(a, b) = \text{Pos}_{0,1}(b, a \vee a)$$

holds.

Recall that by Remark 2.6 there is an equivalence

$$\text{Pos}_{0,1} \simeq \text{Flat}(\text{Pos}_{0,1}^{op}, \text{Set})$$

of categories that we will use now: the flat functor $I : (\text{Pos}_{0,1})^{op} \to \text{Set}$ that is the carrier of the final coalgebra for $M \otimes -$ is transferred by the above equivalence to the poset

$$I \ast E$$

see Remark 2.6. We define now the map

$$\text{beh} : I \ast E \to [0, 1]$$

where $[0, 1]$ is the unit interval with the coalgebra structure described in Example 4.1.

The mapping $\text{beh}$ assigns to the equivalence class

$$([(a_\bullet, m_\bullet)], x \in a_0) \in I \ast E$$

a dyadic expansion that encodes the behaviour of $x \in a_0$ as follows: we know that a complex $(a_\bullet, m_\bullet)$ is a chain

$$m_1 : a_0 \to a_1 \vee a_1, \quad m_2 : a_1 \to a_2 \vee a_2, \quad \ldots, \quad m_i : a_i \to a_{i+1} \vee a_{i+1}, \quad \ldots$$

of morphisms in $\text{Pos}_{0,1}$. The morphism $m_1$ sends $x$ to the left-hand copy or to the right-hand copy of $a_1$, so it gives rise to a binary digit $k_1 \in \{0, 1\}$ and a new element $x_1 \in a_1$. (If $m_1(x)$ is in the glueing of the two copies of $a_1$, choose 0 or 1 arbitrarily). Iterating gives a binary representation $0.k_1k_2\ldots$ of an element of $[0, 1]$.

We will prove that $\text{beh}$ is well-defined and a bijection.

1. **$\text{beh}$ is well-defined:** Let $([(a_\bullet, m_\bullet)], x \in a_0) = [(a'_\bullet, m'_\bullet)], x' \in a'_0]$, then there is an element $[([c_\bullet, q_\bullet]), y \in c_0]$ of the colimit and a zig-zag:

$$\begin{array}{ccc}
    a_0 & \xrightarrow{m_1} & a_1 \vee a_1 \\
    \downarrow & & \downarrow \\
    c_0 & \xrightarrow{q_1} & c_1 \\
    \downarrow & & \downarrow \\
    a'_0 & \xrightarrow{m'_1} & a'_1 \vee a'_1 \\
\end{array} \quad \text{and} \quad \begin{array}{ccc}
    a_1 & \xrightarrow{m_2} & a_2 \vee a_2 \\
    \downarrow & & \downarrow \\
    c_1 & \xrightarrow{q_2} & c_2 \\
    \downarrow & & \downarrow \\
    a'_1 & \xrightarrow{m'_2} & a'_2 \vee a'_2 \\
\end{array}$$

such that all the squares to be commutative.

Observe that, in order to have the commutativity of the above squares, the morphisms $m_i, q_i, m'_i, i = 1, 2, \ldots$ must have the same “behaviour”. This means that if, e.g., the morphism $m_1$ sends $x$ to the left-hand copy of $a_1 \vee a_1$ then also the $q_1, m'_1$ will send the corresponding elements to the left-hand copy of $c_1 \vee c_1$ and $a'_1 \vee a'_1$ respectively. So, we take the same binary representation in $[0, 1]$, i.e., the equality

$$\text{beh}([(a_\bullet, m_\bullet)], x \in a_0) = \text{beh}([(a'_\bullet, m'_\bullet)], x' \in a'_0)$$

holds.
(2) beh is one to one: The key-point here is that there is a morphism \( f : 5 \to 5 \vee 5 \), where 5 is the linear order with five elements, such that for each \( m_i : a_i \to a_{i+1} \vee a_{i+1} \) there is a commutative square

\[
\begin{array}{c}
\begin{array}{c}
a_i \\
\end{array}
\end{array}
\xymatrix{
& a_{i+1} \vee a_{i+1} \\
5 
\ar_{a_i}^{m_i} 
r \ar_{f}^{h'} \ar^{h} \\
5 \vee 5
\end{array}
\]

Suppose that \( \{0, t_1, t_2, t_3, 1\} \) are the elements of 5, then the elements of \( 5 \vee 5 \) will be denoted by \( \{0, t_1^L, t_1^R, t_2, t_3, 1\} \).

We define:

\[
f(t) = \begin{cases} 
0, & \text{if } t = 0 \\
1, & \text{if } t = 1 \\
\frac{t_1^L}{t_2^L}, & \text{if } t = t_1 \\
\frac{t_1^R}{t_2^R}, & \text{if } t = t_3 \\
c, & \text{if } t = t_2
\end{cases}
\]

\[
h(x) = \begin{cases} 
0, & \text{if } m_1(x) = 0 \\
1, & \text{if } m_1(x) = 1 \\
t_1, & \text{if } m_1(x) \in a_{i+1}^L \\
t_3, & \text{if } m_1(x) \in a_{i+1}^R \\
t_2, & \text{if } m_1(x) = c
\end{cases}
\]

where \( L, R \) denotes the left-hand and the right-hand copy and \( c, c' \) are the glueing points of \( a_{i+1} \vee a_{i+1} \) and \( 5 \vee 5 \), respectively. From the above it is easy to verify the commutativity of the square.

Now, if \( \text{beh}([a_*, m_*]) \in \text{beh}([b_*, n_*]) \) for \( x \in a_0 \), i.e., if the binary representations are the same, without loss of generality we can choose the \( m_i \) and \( n_i \) to send the \( x_i \), \( y_i \) to the same copy left-hand or right-hand, respectively. (Hence we avoid the case one of them sending an element to the glueing point). Using commutativity of the above square we have that all the following squares commute:

\[
\begin{array}{c}
\begin{array}{c}
a_0 \\
\end{array}
\end{array}
\xymatrix{
& a_1 \vee a_1 \\
5 
\ar_{a_0}^{m_1} 
r \ar_{f}^{h'} \ar^{h} \\
5 \vee 5
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
a_1 \\
\end{array}
\end{array}
\xymatrix{
& a_2 \vee a_2 \\
5 \vee 5 
\ar_{a_1}^{m_2} 
r \ar_{f}^{h'} \ar^{h} \\
5 \vee 5
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
b_0 \\
\end{array}
\end{array}
\xymatrix{
& b_1 \vee b_1 \\
5 
\ar_{b_0}^{n_1} 
r \ar_{h'} \ar^{h} \\
b_1 \vee b_2
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
b_1 \\
\end{array}
\end{array}
\xymatrix{
& b_2 \vee b_2 \\
5 \vee 5 
\ar_{b_1}^{n_2} 
r \ar_{h'} \ar^{h} \\
5 \vee 5
\end{array}
\]

From this we deduce that there is a zig-zag between the two complexes, \( (a_*, m_*) \), \( (b_*, n_*) \). Therefore, the equality

\[
[(a_*, m_*)] = [(b_*, n_*)]
\]

holds.

(3) beh is \( \text{epi} \): For each binary representation \( 0.k_1k_2\ldots \) of an element of \( [0, 1] \) we can find an element of the colimit, using the three-element linear order 3, and a sequence

\[
m_1 : 3 \to 3 \vee 3, \quad m_2 : 3 \to 3 \vee 3, \quad \ldots \quad m_i : 3 \to 3 \vee 3, \quad \ldots
\]

of morphisms, where each \( m_i \) assigns the middle element of 3, to the middle element in the left-hand copy of 3 \( \vee 3 \) if \( k_i = 0 \), or the middle element in the right-hand copy if \( k_i = 1 \).

In the realm of locally finitely presentable categories, every finitary endofunctor admits a final coalgebra. The well-known technique for proving this result is that of 2-categorical limits of locally finitely presentable categories, see, e.g., [MPa] or [AR].

Our technique will allow us to give an alternative proof of this theorem, see Corollary 4.15 below. In fact, the colimit of (4.2) gives an explicit description of a final coalgebra.

**Corollary 4.15.** Every finitary endofunctor of a locally finitely presentable category admits a final coalgebra.

**Proof.** Recall that the category of the form \( \text{Flat}(\mathcal{A}, \text{Set}) \) is locally finitely presentable, if the category \( \mathcal{A} \) has all finite limits. Denote by \( (\mathcal{A}, M) \) the corresponding self-similarity system. We need to show that \( \text{Complex}(M) \) is cofiltered.

(1) The category \( \text{Flat}(\mathcal{A}, \text{Set}) \cong \text{Lex}(\mathcal{A}, \text{Set}) \) has an initial object, \( \bot \), say. Hence the unique morphism \( ! : \bot \to M \otimes \bot \) is a coalgebra and the category \( \text{Complex}(M) \) is nonempty by Lemma 4.7.

(2) By Proposition 4.6, the category \( \text{Complex}(M) \) has cones for nonempty finite diagrams. Now use Theorem 4.12. \( \square \)
Theorem 4.12 provides us with a concrete description of the final coalgebra as the colimit of the filtered diagram

\[
\left( \text{Complex}(M) \right)^{\text{op}} \xrightarrow{\text{pr}_0^\text{op}} \mathcal{A}^{\text{op}} \xrightarrow{\mathcal{Y}} [\mathcal{A}, \text{Set}]
\]

From that one can easily deduce, for example, the well-known description of the final coalgebra for the endofunctor \( X \mapsto X \times X + A \) on \( \text{Set} \) that we gave in the Introduction.

5. The Weak Solvability Condition

Cofilteredness of the category \( \text{Complex}(M) \) may be hard to verify in the absence of finite limits in \( \mathcal{A} \). We give here a weaker condition that is easier to verify. In particular, we are going to replace the Strong Solvability Condition by a condition of the same type but “holding just on the head of complexes”. This whole section is devoted to finding conditions of “how to propagate from the head of a complex to the whole complex”. Proving the existence of a final coalgebra will require though some extra finiteness condition on the module \( M \), see Definition 5.9. Our condition is a weakening of that considered by Tom Leinster [Le1] in connection with self-similar objects in topology. The main result of this section, Theorem 5.14, then shows that this finiteness condition allows us to conclude that a final coalgebra exists. Our argument applies to self-similarity systems considered by Tom Leinster [Le1] and therefore strengthens his result on the existence of final coalgebras for self-similarity systems.

The key tool for the propagation technique is “König’s Lemma for preorders”, see Theorem 5.6 below. The result relies on a topological fact proved by Arthur Stone in [S].

To be able to state the weak condition we first need to generalize filteredness of a category to filteredness of a functor.

**Definition 5.1.** A functor \( F : \mathcal{X} \rightarrow \mathcal{Y} \) is called filtering, if there exists a cocone for the composite \( F \cdot D \), for every functor \( D : \mathcal{D} \rightarrow \mathcal{X} \) with \( \mathcal{D} \) finite.

A functor \( F \) is called cofiltering if \( F^{\text{op}} \) is filtering.

**Remark 5.2.** Hence a category \( \mathcal{X} \) is filtered if and only if the identity functor \( \text{Id} : \mathcal{X} \rightarrow \mathcal{X} \) is filtering.

A natural candidate for a weaker form of solvability condition is the following one.

**Definition 5.3.** We say that \((\mathcal{A}, M)\) satisfies the Weak Solvability Condition if the functor

\[
\text{pr}_0 : \text{Complex}(M) \rightarrow \text{Complex}_0(M)
\]

is cofiltering.

In particular, observe that the Weak Solvability Condition holds when the category \( \mathcal{A} \) is cofiltered.

**Remark 5.4.** In elementary terms, the Weak Solvability Condition says the following three conditions:

1. The category \( \mathcal{A} \) is non-empty.
2. For every pair \((a\bullet, m\bullet), (a'\bullet, m'\bullet)\) in \( \text{Complex}(M) \) there is a span

\[
\begin{array}{ccc}
   & & a_0 \\
   \downarrow f & & \downarrow \circ \downarrow f' \\
   b & & a'_0
\end{array}
\]

in \( \mathcal{A} \).

3. For every parallel pair of the form

\[
\begin{array}{ccc}
   (a\bullet, m\bullet) & \xrightarrow{(u\bullet)} & (a'\bullet, m'\bullet)
\end{array}
\]

in \( \text{Complex}(M) \) there is a fork

\[
\begin{array}{ccc}
   b & \xrightarrow{f} & a_0 \\
   \downarrow u_0 & & \downarrow v_0 \\
   a'_0 & \xrightarrow{v_0}
\end{array}
\]

in \( \mathcal{A} \).

Observe that, since we assume that \( \text{Complex}(M) \) is nonempty (Assumption 4.10), the above condition (1) is satisfied: the category \( \mathcal{A} \) is nonempty.
Observe that if \((\mathcal{A}, M)\) satisfies the Strong Solvability Condition, it does satisfy the Weak Solvability Condition. In fact, in this case every functor \(\text{pr}_n : \text{Complex}(M) \to \text{Complex}_n(M)\) is cofiltering. The following result shows that the Weak Solvability Condition can be formulated in this way.

**Proposition 5.5.** The following are equivalent:

1. The Weak Solvability Condition.
2. The functors \(\text{pr}_n : \text{Complex}(M) \to \text{Complex}_n(M)\) are cofiltering for all \(n \geq 0\).

**Proof.** That (2) implies (1) is clear. To prove the converse, we need to verify the following three properties:

(a) Every category \(\text{Complex}_n(M)\) is non-empty. This is clear: we assume that that \(\text{Complex}(M)\) is non-empty, see Assumption 4.10.

(b) Every pair \(\text{pr}_n(a\bullet, m\bullet), \text{pr}_n(a'\bullet, m'\bullet)\) in \(\text{Complex}_n(M)\) has a cone.

Observe that, due to Weak Solvability Condition applied at stage \(n\), we have the following diagram

\[
\begin{array}{ccc}
\cdots & \cdots & \cdots \\
\downarrow & \downarrow & \downarrow \\
M(a_0) & M(a_1) & M(a_2) \\
\end{array}
\]

Since the functor \(M(b_n, -)\) is flat, the pair \(m_n \circ f_n \in M(b_n, a_{n-1})\) has a cone:

\[
\begin{array}{ccc}
\cdots & \cdots & \cdots \\
\downarrow & \downarrow & \downarrow \\
M(a_0) & M(a_1) & M(a_2) \\
\end{array}
\]

If we proceed like this down to zero we obtain the desired vertex \((b\bullet, u\bullet)^{(n)}\) in \(\text{Complex}_n(M)\):

\[
\begin{array}{ccc}
\cdots & \cdots & \cdots \\
\downarrow & \downarrow & \downarrow \\
M(a_0) & M(a_1) & M(a_2) \\
\end{array}
\]

(c) For every parallel pair of the form

\[
\begin{array}{ccc}
\cdots & \cdots & \cdots \\
\downarrow & \downarrow & \downarrow \\
M(a_0) & M(a_1) & M(a_2) \\
\end{array}
\]

in \(\text{Complex}_n(M)\), there is a fork.

Consider the following diagram:

\[
\begin{array}{ccc}
\cdots & \cdots & \cdots \\
\downarrow & \downarrow & \downarrow \\
M(a_0) & M(a_1) & M(a_2) \\
\end{array}
\]

Again, start at stage \(n\), use the Weak Solvability Condition there to obtain \(f_n\), and then use flatness of \(M(b_n, -)\) to obtain \(l_n\), and \(f_{n-1}\). Proceed like this down to zero and obtain the desired fork

\[
\begin{array}{ccc}
\cdots & \cdots & \cdots \\
\downarrow & \downarrow & \downarrow \\
M(a_0) & M(a_1) & M(a_2) \\
\end{array}
\]

in \(\text{Complex}_n(M)\).

This finishes the proof.
In the proof that the Weak Solvability Condition implies the Strong one, we will need to use “König’s Lemma” for preorders that we formulate in Theorem 5.6 below.

Recall that a preorder \((X, \sqsubseteq)\) is a set \(X\) equipped with a reflexive, transitive binary relation \(\sqsubseteq\).

Recall also that a subset \(B \subseteq X\) of a preorder is called downward-closed, if for every \(b \in B\) and \(b' \sqsubseteq b\) we have \(b' \in B\). The dual notion is called upward-closed.

A subset \(S\) of a preorder \((X, \sqsubseteq)\) is called final if for every \(x \in X\) there exists \(s \in S\) with \(x \sqsubseteq s\).

**Theorem 5.6.** Suppose that

\[
\cdots \rightarrow \mathcal{P}_{n+1} \xrightarrow{p_{n+1}^n} \mathcal{P}_n \xrightarrow{p_{n-1}^n} \cdots \xrightarrow{p_0^n} \mathcal{P}_0
\]  

(5.1)

is a chain of preorders and monotone maps, that satisfies the following two conditions:

1. Every \(\mathcal{P}_n\) has a nonempty finite final subset.
2. The image of any upward-closed set under \(p_{n+1}^n : \mathcal{P}_{n+1} \rightarrow \mathcal{P}_n\) is upward-closed.

Then the limit \(\lim_n \mathcal{P}_n\) is nonempty, i.e., there is a sequence \((x_n)\) with \(p_{n+1}^n(x_{n+1}) = x_n\) holding for every \(n \geq 0\).

The proof of Theorem 5.6 will rely on some facts from General Topology that we recall now. As a reference to topology we refer to the book [En].

Recall that every preorder \((X, \sqsubseteq)\) can be equipped with the lower topology \(\tau_{\sqsubseteq}\), if we declare the open sets to be exactly the downward closed sets.

Remark 5.7. Of course, Theorem 5.6 holds whenever Conditions (1) and (2) hold “cofinally”, i.e., whenever there exists \(n_0\) such that Conditions (1) and (2) hold for all \(n \geq n_0\).

**Notation 5.8.** For any diagram \(D : \mathcal{D} \rightarrow \text{Complex}(M)\) with \(\mathcal{D}\) finite, let \(\mathcal{D}^\mathcal{P}_n\) denote the following preorder:

1. Points of \(\mathcal{P}_n^\mathcal{D}\) are cones for the composite \(p_{n,n} : \mathcal{P}_n \rightarrow \text{Complex}_{\mathcal{P}_n}(M)\).
2. The relation \(c \subseteq n c'\) holds in \(\mathcal{D}^\mathcal{P}_n\) if and only if the cone \(c\) factors through the cone \(c'\).

For each \(n \geq 0\) denote by \(p_{n+1}^n : \mathcal{D}^\mathcal{P}_{n+1} \rightarrow \mathcal{D}^\mathcal{P}_n\)

the obvious restriction map and observe that it is monotone.

Also observe that the Weak Solvability Condition guarantees that every preorder \(\mathcal{D}^\mathcal{P}_n\) is nonempty by Proposition 5.5. The Weak Solvability Condition alone does not imply the Strong one — the self-similarity system \((\mathcal{A}, M)\) has to fulfill additional conditions that will allow us to apply Theorem 5.6.

**Definition 5.9.** We say that the module \(M\) is compact, if the preorder \(\mathcal{D}^\mathcal{P}_n\) has a nonempty finite final subset, for each \(n \geq 0\) and each finite nonempty diagram \(D : \mathcal{D} \rightarrow \text{Complex}(M)\).

First we give easy examples of compact modules.

**Example 5.10.**

1. Every module \(M\) on a finitely complete category \(\mathcal{A}\) is compact: in fact, in this case every preorder \(\mathcal{D}^\mathcal{P}_n\) has a one-element final set.
2. If the module \(M\) is finite in the sense of \([Le_1]\), i.e., if every functor \(M(-,b) : \mathcal{A}^{op} \rightarrow \text{Set}\) has a finite category of elements, then it is compact.

Nontrivial examples of compact modules will follow later from Proposition 5.12, see Example 5.13. We need to recall the concept of a factorization system for cocones first. For details, see, e.g., Chapter IV of [AHS].

**Definition 5.11.** Let \(\mathcal{K}\) be a finitely accessible category.

1. We say that a cocone \(c_d : Dd \rightarrow X\) is jointly epi if, for every parallel pair \(u, v\), the equality \(u \cdot c_d = v \cdot c_d\) for all \(d\) implies that \(u = v\) holds.
Proposition 5.12. Suppose the finitely accessible category \( \mathcal{K} \) satisfies the following conditions:

1. \( \mathcal{K} \) is a (finite jointly epi, extremal mono)-category.
2. \( \mathcal{K}_{fp} \) is finitely cowellpowered.

Suppose that a finitary functor \( \Phi : \mathcal{K} \rightarrow \mathcal{K} \) preserves extremal monos. Then the flat module corresponding to \( \Phi \) is compact.

Proof. We will use the description of complexes from Remark 3.5.

Let \( D : \mathcal{D} \rightarrow \text{Complex}(M) \) be a finite nonempty diagram. Choose any \( n \geq 0 \) and denote the value of the composite \( \text{pr}_n \cdot D \) by commutative squares

\[
\begin{array}{ccc}
pr_n \cdot Dd & \delta_0 & \Phi(a_1^d) \\
pr_n \cdot Dd & \delta_0 & \Phi(a_1^d) \\
\end{array}
\]

in \( \mathcal{K} \). We will construct the finite nonempty initial (notice the change of the variance: \( \mathcal{A} \) is \( \mathcal{K}_{fp}^{op} \)) of cocones for \( \text{pr}_n \cdot D \) by proceeding from \( i = n - 1 \) downwards to 0 as follows:

For every jointly epi cocone \( e_{i+1} : a_{i+1}^d \rightarrow z_{i+1} \) choose all jointly epi cocones \( e_i^d : a_i^d \rightarrow z_i \) and all connecting morphisms \( c_{i+1} : z_i \rightarrow \Phi(z_{i+1}) \) making the following diagram

\[
\begin{array}{c}
z_i \quad z_{i+1} \quad \Phi(z_{i+1}) \\
\Phi(e_{i+1}) \quad \Phi(e_{i+1}) \\
\end{array}
\]

commutative. Observe that there is at least one such pair: the factorization of the cocone \( \Phi(e_{i+1}^d) \cdot m_{i+1}^d \) into a jointly epi and extremal mono. Since every cocone \( e_i^d \) is jointly epi, the corresponding \( c_{i+1} \) is determined uniquely.

We claim that the above nonempty finite family of cocones for \( \text{pr}_n \cdot D \) is initial. To that end, consider any cocone

\[
\begin{array}{ccc}
w_0 \quad w_1 \quad w_2 \quad \cdots \quad w_n \\
\Phi(w_1) \quad \Phi(w_2) \quad \cdots \quad \Phi(w_n) \\
\end{array}
\]
for $\text{pr}_n \cdot D$. Factorize the cocone $g^D_n$ into a jointly epi $e^D_n : a^D_n \rightarrow z_n$ followed by an extremal mono $j_n : z_n \rightarrow w_n$. Do the same thing for the cocone $g^D_{n-1}$ and then use the diagonalization property to obtain the desired $c_n : z_{n-1} \rightarrow \Phi(z_n)$

\[
\begin{array}{c}
\begin{array}{c}
\text{w}_{n-1} \\
j_{n-1}
\end{array}
\begin{array}{c}
\text{w}_n \\
\Phi(j_n)
\end{array}
\begin{array}{c}
\text{z}_{n-1} \\
c_n
\end{array}
\begin{array}{c}
\Phi(c_n) \\
a^D_{n-1}
\end{array}
\end{array}
\]

using the fact that $\Phi(j_n)$ is extremal mono by assumption. Proceed like this downwards to 0 and obtain thus one of the above chosen cocones through which the given cocone of $g$ factorizes. \[\square\]

**Example 5.13.** Recall from Example 2.4(5) that the category $\text{Lin}$ of all linear orders and all monotone maps is finitely accessible. We indicate that it fulfills the assumptions of the above proposition and give several examples of finitary endofunctors that preserve extremal monos.

(1) Jointly epi cocones $e^D : Dd \rightarrow X$ are exactly those where (the underlying set of) $X$ is the union of the images of all $Dd$.

(2) A monotone map $j : A \rightarrow B$ is an extremal mono if and only if $j$ is injective and the linear order on $A$ is that induced by $B$.

From the above it is clear that $\text{Lin}$ is a (finite jointly epi, extremal mono)-category and that $\text{Lin}_{fp}$ is finitely cowellpowered.

To give various examples of functors that preserve extremal monos, we need to introduce the following notation: given linear orders $X$ and $Y$ we denote by $X ; Y$ (read: $X$ then $Y$) the linear order on the disjoint union of (the underlying sets of) $X$ and $Y$ by putting every element of $X$ to be lower than any element of $Y$ and leaving the linear orders of $X$ and $Y$ unchanged.

The second construction is that of ordinal product, by $X * Y$ we denote the linear order on the cartesian product of (underlying sets of) $X$ and $Y$ where we replace each element of $Y$ by a disjoint copy of $X$. More precisely, $(x, y) < (x', y')$ holds if and only if either $x < x'$ holds or $x = x'$ and $y < y'$.

It can be proved easily that, for example, the following two assignments $X \mapsto X * \omega$, $X \mapsto (X * \omega) ; 1$ where $\omega$ is the first countable ordinal and 1 denotes the one-element linear order, are finitary functors and they both preserve extremal monos.

Our main result on compact modules is the following one.

**Theorem 5.14.** Suppose that $M$ is a compact module. Then the Weak Solvability Condition implies the Strong one.

**Proof.** We know that $\text{Complex}(M)$ is nonempty by Assumption 4.10. We have to construct a cone for every diagram $D : D \rightarrow \text{Complex}(M)$ with $D$ finite nonempty.

Form the corresponding chain

\[
\cdots \rightarrow \mathcal{D}_{n+1}^D \xrightarrow{p_{n+1}^D} \mathcal{D}_n^D \xrightarrow{p_{n-1}^D} \cdots \xrightarrow{p_1^D} \mathcal{D}_0^D
\]

of preorders and monotone maps. We will verify first that it satisfies Conditions (1) and (2) of Theorem 5.6.

(1) Each $\mathcal{D}_n^D$ contains a nonempty finite final subset since the module $M$ is assumed to be compact.
\(2\) The image of every upward-closed set under the monotone map \(p_n^{n+1}\) is upward-closed.

Denote the value of \(D : \mathcal{P} \rightarrow \text{Complex}(M)\) by

\[
\begin{array}{c}
\text{Dd} \\
\downarrow D\delta \\
\text{Dd'}
\end{array}
\xrightarrow{\begin{array}{c}
m_1 \\
n_2 \\
m_3 \\
m_4
\end{array}}
\xrightarrow{\begin{array}{c}
a'_1 \\
a'_2 \\
a'_3 \\
a'_4
\end{array}}
\xrightarrow{\begin{array}{c}
a_1 \\
a_2 \\
a_3 \\
a_4
\end{array}}
\xrightarrow{\begin{array}{c}
a_1' \\
a_2' \\
a_3' \\
a_4'
\end{array}}
\xrightarrow{\begin{array}{c}
a_0 \\
a_0'
\end{array}}
\]

Then the value of \(\text{pr}_n \cdot D : \mathcal{P} \rightarrow \text{Complex}_n(M)\) is given by

\[
\begin{array}{c}
\text{pr}_n \cdot \text{Dd} \\
\downarrow \text{pr}_n \cdot D\delta \\
\text{pr}_n \cdot \text{Dd'}
\end{array}
\xrightarrow{\begin{array}{c}
m_1 \\
n_2 \\
m_3 \\
m_4
\end{array}}
\xrightarrow{\begin{array}{c}
a'_1 \\
a'_2 \\
a'_3 \\
a'_4
\end{array}}
\xrightarrow{\begin{array}{c}
a_1 \\
a_2 \\
a_3 \\
a_4
\end{array}}
\xrightarrow{\begin{array}{c}
a_1' \\
a_2' \\
a_3' \\
a_4'
\end{array}}
\xrightarrow{\begin{array}{c}
a_0 \\
a_0'
\end{array}}
\]

for every \(n \geq 0\).

Choose an upward-closed set \(S \subseteq \mathcal{P}^{n+1}\). Every \(s \in S\) is a cone for the above diagram \(\text{pr}_{n+1} \cdot D\) and we denote this cone by

\[
\begin{array}{c}
s_{n+1} \\
\downarrow \sigma_{n+1} \\
a_{n+1} \\
\end{array}
\xrightarrow{\begin{array}{c}
m_1 \\
n_2 \\
m_3 \\
m_4
\end{array}}
\xrightarrow{\begin{array}{c}
a'_1 \\
a'_2 \\
a'_3 \\
a'_4
\end{array}}
\xrightarrow{\begin{array}{c}
a_1 \\
a_2 \\
a_3 \\
a_4
\end{array}}
\xrightarrow{\begin{array}{c}
a_1' \\
a_2' \\
a_3' \\
a_4'
\end{array}}
\xrightarrow{\begin{array}{c}
a_0 \\
a_0'
\end{array}}
\]

Choose any \(s \in S\) and consider \(b\) in \(\mathcal{P}^{n+1}\) such that \(p_n^{n+1}(s) \subseteq b\) holds. We need to find \(s \subseteq t\) such that \(p_n^{n+1}(t) = b\).

In our notation, \(b\) has the form

\[
\begin{array}{c}
b_n \\
\downarrow \beta_n \\
a_n \\
\end{array}
\xrightarrow{\begin{array}{c}
m_1 \\
n_2 \\
m_3 \\
m_4
\end{array}}
\xrightarrow{\begin{array}{c}
a'_1 \\
a'_2 \\
a'_3 \\
a'_4
\end{array}}
\xrightarrow{\begin{array}{c}
a_1 \\
a_2 \\
a_3 \\
a_4
\end{array}}
\xrightarrow{\begin{array}{c}
a_1' \\
a_2' \\
a_3' \\
a_4'
\end{array}}
\xrightarrow{\begin{array}{c}
a_0 \\
a_0'
\end{array}}
\]

The inequality \(p_n^{n+1}(s) \subseteq b\) means that there exists a diagram of the form

\[
\begin{array}{c}
s_n \\
\downarrow g_n \\
b_n \\
\end{array}
\xrightarrow{\begin{array}{c}
m_1 \\
n_2 \\
m_3 \\
m_4
\end{array}}
\xrightarrow{\begin{array}{c}
a'_1 \\
a'_2 \\
a'_3 \\
a'_4
\end{array}}
\xrightarrow{\begin{array}{c}
a_1 \\
a_2 \\
a_3 \\
a_4
\end{array}}
\xrightarrow{\begin{array}{c}
a_1' \\
a_2' \\
a_3' \\
a_4'
\end{array}}
\xrightarrow{\begin{array}{c}
a_0 \\
a_0'
\end{array}}
\]

where the equalities \(\beta_i \cdot g_i = \sigma_i\) hold for every \(i \in \{0, \ldots, n\}\).

Consider the following diagram:
Thus, the desired $t$ has the form
\[
\begin{array}{cccccccc}
s_{n+1} & \xrightarrow{g_n \circ m_n^a} & b_n & \xrightarrow{m_n^b} & \ldots & \xrightarrow{m_2^b} & b_2 & \xrightarrow{m_1^b} & b_0 \\
\beta_n & \downarrow & \beta_n & \downarrow & \beta_2 & \downarrow & \beta_2 & \downarrow & \beta_0 \\
a_{n+1} & \xrightarrow{m_{n+1}^d} & a_n & \xrightarrow{m_n^d} & \ldots & \xrightarrow{m_3^d} & a_2 & \xrightarrow{m_1^d} & a_0
\end{array}
\]

Hence the image of every upward-closed set under the monotone map $p_{n+1}^D : \mathcal{D}_{n+1} \longrightarrow \mathcal{D}_n$ is upward-closed.

Therefore, by Theorem 5.6, we have an element $(x_n)$ of the limit lim $\mathcal{D}_n$.

Denote every $x_n$ as follows:
\[
x_n = \begin{pmatrix} x_n^0 \\ \chi_0^{n,d} \\ a_n^0 \\ m_n^0 \\ \chi_1^{n,d} \\ \chi_2^{n,d} \\ a_2^0 \\ m_2^0 \\ \chi_3^{n,d} \\ x_3^0 \end{pmatrix}
\]

From that we can define a complex
\[
\ldots \xrightarrow{m_4^4} x_3^1 \xrightarrow{m_3^3} x_2^2 \xrightarrow{m_2^2} x_1^3 \xrightarrow{m_1^4} x_0^4
\]
that is obviously a vertex of a cone for $D : \mathcal{D} \longrightarrow \text{Complex}(M)$. \hfill \Box

**Corollary 5.15.** Every compact module satisfying the Weak Solvability Condition has a final coalgebra.

**Example 5.16.** Recall from Example 5.13 that the modules corresponding to the finitary endofunctors $X \mapsto X * \omega$, $X \mapsto (X * \omega) : 1$ of the category $\text{Lin}$ are compact. Since $\text{Lin}$ satisfies the Weak Solvability Conditions, the above two functors have final coalgebras by the above corollary. The linear orders of these coalgebras are the continuum and Cantor space, respectively, see [PP] for a proof.

### 6. What the Existence of a Final Coalgebra Entails

We show in this section that the existence of final coalgebras entails the Weak Solvability Condition, provided the module is pointed. As a corollary, we derive a necessary condition on the category $\mathcal{A}$ so that the identity functor on $\text{Flat}(\mathcal{A}, \text{Set})$ admits a final coalgebra, see Corollary 6.4.

**Assumption 6.1.** We assume that in this section that $M$ is pointed, i.e., that $M$ is equipped with a module morphism $c : \mathcal{A} \longrightarrow M$.

Of course, the assumption is clearly satisfied if and only if, when passing from $M$ to the finitary endofunctor $\Phi$, there exists a natural transformation $\text{Id} \longrightarrow \Phi$.

**Remark 6.2.** From the Assumption 6.1 it follows that every representable functor $\mathcal{A}(a, -)$ admits a coalgebra structure
\[
c_a : \mathcal{A}(a, -) \longrightarrow M(a, -)
\]
for $M \otimes -$ (we used that $(M \otimes \mathcal{A})(a, -) \cong M(a, -)$ holds). This of course entails that $\text{Complex}(M)$ is nonempty, see Lemma 4.7.

Moreover, for every $f : a \longrightarrow a'$, the natural transformation $\mathcal{A}(f, -) : \mathcal{A}(a', -) \longrightarrow \mathcal{A}(a, -)$ is a coalgebra morphism, i.e., the square
\[
\begin{array}{ccc}
\mathcal{A}(a', -) & \xrightarrow{c_{a'}} & M(a', -) \\
\mathcal{A}(f, -) & \downarrow & \downarrow M(f, -) \\
\mathcal{A}(a, -) & \xrightarrow{c_a} & M(a, -)
\end{array}
\]
commutes.

**Theorem 6.3.** Suppose that $M$ is pointed and suppose that a final coalgebra for $M \otimes -$ exists. Then $\text{pr}_0$ is cofiltering, i.e., the Weak Solvability Condition holds.
Proof. Let us denote by \( j : J \rightarrow M \otimes J \) the final coalgebra for \( M \otimes - \).

Denote by \( c^1_a : \mathcal{A}(a, -) \rightarrow J \) the unique coalgebra morphism such that the square

\[
\begin{array}{ccc}
\mathcal{A}(a, -) & \xrightarrow{c_a} & M \otimes \mathcal{A}(a, -) \\
\downarrow c^1_a & & \downarrow M \circ c^1_a \\
J & \xrightarrow{j} & M \otimes J
\end{array}
\]

commutes.

Then the following triangle

\[
\begin{array}{ccc}
\mathcal{A}(a', -) & \xrightarrow{c^1_{a'}} & J \\
\downarrow \mathcal{A}(f, -) & & \downarrow c^1_a \\
\mathcal{A}(a, -) & \xrightarrow{\mathcal{A}(f, -)} & J
\end{array}
\]

commutes by finality of \( j : J \rightarrow M \otimes J \) and the square (6.1).

Recall that, in any case, one can form a colimit \( I \) of the diagram

\[
\begin{array}{ccc}
(\text{Complex}(M))^{\text{op}} & \xrightarrow{pr_0^{\text{op}}} & \mathcal{A}^{\text{op}} \xrightarrow{\mathcal{Y}} [\mathcal{A}, \text{Set}]
\end{array}
\]

We do not claim that \( I : \mathcal{A} \rightarrow \text{Set} \) is flat. In fact, we will just use the fact that \( I \) is a colimit. For observe that so far we have proved that the collection of morphisms

\[ c^1_{pr_0^{\text{op}}(a_*, m_*)} : \mathcal{A}(a_0, -) \rightarrow J \]

forms a cocone for the diagram \( \mathcal{Y} \cdot pr_0^{\text{op}} \). Hence there exists a natural transformation

\[ \overline{\beta} : I \rightarrow J \]

The natural transformation \( \overline{\beta} \) induces a functor \( F : \text{Complex}(M) \rightarrow \text{elts}(J) \) by putting

\[ (a_*, m_*) \mapsto x \in J a_0 \]

where the element \( x \in J a_0 \) corresponds to the natural transformation \( c^1_{pr_0^{\text{op}}(a_*, m_*)} : \mathcal{A}(a_0, -) \rightarrow J \) by Yoneda Lemma.

Then the diagram

\[
\begin{array}{ccc}
\text{Complex}(M) & \xrightarrow{F} & \text{elts}(J) \\
\downarrow pr_0 & & \downarrow \mathcal{Y} \\
\mathcal{A} & \xrightarrow{\mathcal{Y}} & [\mathcal{A}, \text{Set}]
\end{array}
\]

commutes. Since \( J \) is a flat functor, the category \( \text{elts}(J) \) is cofiltered. Hence \( pr_0 = \text{proj} \cdot F \) is a cofiltering functor.

\[ \square \]

Corollary 6.4. If the identity functor on the category \( \text{Flat}(\mathcal{A}, \text{Set}) \) has a final coalgebra, then the category \( \mathcal{A} \) must be cofiltered.

Remark 6.5. The above Corollary shows that the identity endofunctor of a Scott complete category \( \mathcal{K} \), see Example 2.4(6), cannot have a final coalgebra unless the category \( \mathcal{K} \) is in fact locally finitely presentable.

What we have proved so far, allows us to go in full circle:

Corollary 6.6. Suppose that \( M : \mathcal{A} \rightarrow \mathcal{A} \) is a pointed, compact module. Then the following are equivalent:

(1) The self-similarity system \((\mathcal{A}, M)\) satisfies the Weak Solvability Condition.

(2) The self-similarity system \((\mathcal{A}, M)\) satisfies the Strong Solvability Condition.

(3) The colimit of the diagram

\[
\begin{array}{ccc}
(\text{Complex}(M))^{\text{op}} & \xrightarrow{pr_0^{\text{op}}} & \mathcal{A}^{\text{op}} \xrightarrow{\mathcal{Y}} [\mathcal{A}, \text{Set}]
\end{array}
\]

is a flat functor.

(4) The final coalgebra for \( M \otimes - \) exists.
7. Conclusions and Future Research

We have provided a new uniform way of constructing final coalgebras for finitary endofunctors of locally finitely presentable categories. We have argued about the necessity of expanding these results to the case of finitely accessible categories. To that end we have formulated general conditions that are sufficient for the existence of a final coalgebra. We expect that our conditions can be exploited for finding new interesting examples of final coalgebras in accessible categories.

In many concrete examples where the final coalgebra cannot exist for cardinality reasons (e.g., the categories where all maps are injections) we expect that suitable modifications of our results will provide coalgebras of “rational terms”. This means coalgebras comprising of solutions of finitary recursive systems, see [AMV].
